

# HW1 Programming Problem 1 (10 points)

You are given 14 temperature measurements from 14 thermocouples in a factory. A model has produced 14 temperature predictions, one for each thermocouple. You must compute the error vector and MSE between the predicted and measured temperatures via a few methods.

Run the next cell to load the data; then proceed through the notebook.

- `y_data` is  $y$ , a 14x1 array of temperature measurements (in deg C)
- `y_pred` is  $\hat{y}$ , a 14x1 array of temperature predictions

```
In [ ]: import numpy as np
np.set_printoptions(precision=4)

y_data = np.array([[20,21,30,30,21,25,38,37,30,22,22,38,20,35]],dtype=np.double).T
y_pred = np.array([[21,21,31,30,20,28,36,32,31,20,21,39,21,34]],dtype=np.double).T

print("y_data = \n", y_data)
print("y_pred = \n", y_pred)
```

```
y_data =
[[20.]
 [21.]
 [30.]
 [30.]
 [21.]
 [25.]
 [38.]
 [37.]
 [30.]
 [22.]
 [22.]
 [38.]
 [20.]
 [35.]]
y_pred =
[[21.]
 [21.]
 [31.]
 [30.]
 [20.]
 [28.]
 [36.]
 [32.]
 [31.]
 [20.]
 [21.]
 [39.]
 [21.]
 [34.]]
```

## Error vector

First, compute the error vector  $y_{err} = y - \hat{y}$ . Call the result `y_err`. It should be 14x1.

You may do this with a loop, or -- better yet -- by simply subtracting the two arrays.

```
In [ ]: # YOUR CODE GOES HERE
# Compute y_err
y_err = y_data - y_pred

print("Size of y_err:", np.shape(y_err))
```

Size of y\_err: (14, 1)

## Mean squared error (MSE)

Now compute the MSE,

$$MSE = \frac{1}{N} \sum_{i=1}^N (y_i - \hat{y}_i)^2 = \frac{1}{N} \sum_{i=1}^N y_{err}^2$$

### MSE with Loop

First, compute this quantity by using a for loop to loop through `y_err`, performing the necessary operations to compute MSE.

Call the result `MSE_loop`.

Your result should be  $\approx 3.5714$ .

```
In [ ]: # YOUR CODE GOES HERE
# Compute MSE_loop
_ = 0
for error in y_err:
    _ += error*error
MSE_loop = _ / len(y_err)

print("MSE (loop) = ", MSE_loop)
```

MSE (loop) = [3.5714]

## MSE by matrix multiplication

Another way to compute the MSE is by recognizing that the sum  $\sum_{i=1}^N y_{err}^2$  equals the matrix product  $y_{err}' \cdot y_{err}$ .

Therefore:

$$MSE = \frac{1}{N} y_{err}' \cdot y_{err}$$

Compute the MSE this way. Call it `MSE_mm`, and make sure the result is the same. This is a much more efficient way of computing the MSE in Python.

Note that you can compute the transpose of a 2D array `A` with `A.T`, and you can multiply matrices `A` and `B` with `A @ B`.

```
In [ ]: # YOUR CODE GOES HERE
# Compute MSE_mm
MSE_mm = np.matmul(y_err.T, y_err) / len(y_err)

print("MSE (matrix multiplication) = ", MSE_mm)
```

MSE (matrix multiplication) = [[3.5714]]

## MSE by numpy mean

Now you will compute the MSE once more, but using numpy operations. Use `np.mean()` to take an average. Compute the square of `y_err` with either `np.square()` or `y_err * y_err`.

Call your `MSE_np`, and make sure the result is the same. This is also much more efficient than a Python for loop.

```
In [ ]: # YOUR CODE GOES HERE
# Compute MSE_np
MSE_np = np.square(y_err).mean(axis=0)

print("MSE (Numpy) = ", MSE_np)
```

MSE (Numpy) = [3.5714]

```
In [ ]:
```
